

## TEACHING NOTES AND LESSON PLAN FOR “ORDER OF OPERATIONS”.

I like to arrive at BIDMAS after an investigation of **“whether we get the same answer or not when we do operations in different orders”**.

It would be a great shame to just “give the rule”!

You could use the following as a lesson plan if you wish:

Consider these pairs of questions and see if we get the same answers by changing the order.

1.  $3 + 4 + 5$                       or                       $3 + 4 + 5$

$= 7 + 5$      $= 3 + 9$

$= 12$      $= 12$

Clearly, the order did not matter in this case.

2.  $8 - 5 - 1$                       or                       $8 - 5 - 1$

$= 3 - 1$      $= 8 - 4$

$= 2$      $= 4$

We get different answers so the order does matter!

We need to make a rule (or convention) so that we all do the same thing in cases like these above.

**IF A PROBLEM HAS JUST + OR – OR BOTH, WE MUST START FROM THE LEFT.**

eg 3.  $12 - 5 + 2 - 1$

$= 7 + 2 - 1$

$= 9 - 1$

$= 8$

We obviously do not have to write out all these steps every time because we can do most things mentally.

eg 4.  $14 - 6 - 3 - 1$

$= 8 - 3 - 1$

$= 5 - 1$

$= 4$

If we try ANY other order, we will get the wrong answer !

Now consider these pairs of questions:

$$\begin{array}{l}
 5. \quad 3 \times 4 \times 2 \\
 = \quad 12 \times 2 \\
 = \quad 24
 \end{array}
 \quad \text{or} \quad
 \begin{array}{l}
 3 \times 4 \times 2 \\
 = \quad 3 \times 8 \\
 = \quad 24
 \end{array}$$

Clearly, the order did not matter in this case.

$$\begin{array}{l}
 6. \text{ Now consider:} \\
 24 \div 4 \div 2 \\
 = \quad 6 \div 2 \\
 = \quad 3
 \end{array}
 \quad \text{or} \quad
 \begin{array}{l}
 24 \div 4 \div 2 \\
 = \quad 24 \div 2 \\
 = \quad 12
 \end{array}$$

We get **different answers** so the order does matter !

We need to make a rule (or convention) so that we all do the same thing in cases like these above.

IF A PROBLEM HAS JUST  $\times$  OR  $\div$  OR BOTH, WE MUST START FROM THE LEFT.

eg 7

$$\begin{array}{l}
 6 \times 8 \div 4 \\
 = \quad 48 \div 4 \\
 = \quad 12
 \end{array}$$

eg 8.

$$\begin{array}{l}
 12 \div 2 \times 3 \\
 = \quad 6 \times 3 \\
 = \quad 18
 \end{array}$$

NOW SUPPOSE WE HAVE A MIXTURE OF  $+$ ,  $-$ ,  $\times$ ,  $\div$  IN THE SAME PROBLEM!

eg If you buy a packet of cornflakes for \$5 and 3 cans of beans each costing \$2 then the cost could be written as  $5 + 3 \times 2$

Clearly we do NOT start from the left here. The correct cost is  $5 + 6 = \$11$

If we were to start from the left we would get  $8 \times 2 = \$16$

A RULE FOR THIS IS:  $\times$  **COMES BEFORE**  $+$

Basically,  $+$  and  $-$  are equal importance and if a problem only has  $+$  and  $-$  then we just start from the left.

Similarly,  $\times$  and  $\div$  are also of equal importance and if a problem only has  $\times$  and  $\div$  then we also just start from the left.

BUT if a problem has a combination of  $+$ ,  $-$ ,  $\times$  or  $\div$  we must do the  $\times$  and  $\div$  before we do the  $+$  and  $-$ .

$$\begin{aligned} \text{eg 10. } & 2 \times 4 + 3 \\ & \quad \downarrow \\ & = 8 + 3 \\ & = 11 \end{aligned}$$

$$\begin{aligned} 11. & 5 + 6 \times 2 \\ & \quad \downarrow \\ & = 5 + 12 \\ & = 17 \end{aligned}$$

$$\begin{aligned} 12. & 7 \times 2 - 9 \\ & \quad \downarrow \\ & = 14 - 9 \\ & = 5 \end{aligned}$$

$$\begin{aligned} 13. & 9 - 3 \times 2 \\ & \quad \downarrow \\ & = 9 - 6 \\ & = 3 \end{aligned}$$

$$\begin{aligned} 14. & 8 \div 4 + 2 \\ & \quad \downarrow \\ & = 2 + 2 \\ & = 4 \end{aligned}$$

$$\begin{aligned} 15. & 8 - 20 \div 4 \\ & \quad \downarrow \\ & = 8 - 5 \\ & = 3 \end{aligned}$$

$$\begin{aligned} 16. & 9 + 2 \times 3 - 4 \\ & \quad \downarrow \\ & = 9 + 6 - 4 \\ & = 15 - 4 \\ & = 11 \end{aligned}$$

$$\begin{aligned} 17. & 2 \times 3 + 4 \times 5 \\ & \quad \downarrow \quad \downarrow \\ & = 6 + 20 \\ & = 26 \end{aligned}$$

$$\begin{aligned} 18. & 8 \div 2 + 5 \times 2 \\ & \quad \downarrow \quad \downarrow \\ & = 4 + 10 \\ & = 14 \end{aligned}$$

$$\begin{aligned} 19. & 7 + 8 \div 2 - 5 \\ & \quad \downarrow \\ & = 7 + 4 - 5 \\ & = 11 - 5 \\ & = 6 \end{aligned}$$

## **BREAKING THE RULES!**

We can do this by using **BRACKETS**.

The order now is **BRACKETS FIRST**, then  $\times$  and  $\div$ , then lastly  $+$  and  $-$

$$\begin{aligned} 1(a) \quad & 3 + 2 \times 4 \\ & \quad \downarrow \downarrow \\ & = 3 + 8 \\ & = 11 \end{aligned}$$

$$\begin{aligned} (b) \quad & (3 + 2) \times 4 \\ & \quad \downarrow \\ & = 5 \times 4 \\ & = 20 \end{aligned}$$

---

$$\begin{aligned} 2(a) \quad & 18 - 6 \div 3 \\ & \quad \downarrow \\ & = 18 - 2 \\ & = 16 \end{aligned}$$

$$\begin{aligned} (b) \quad & (18 - 6) \div 3 \\ & \quad \downarrow \\ & = 12 \div 3 \\ & = 4 \end{aligned}$$

---

$$\begin{aligned} 3(a) \quad & 8 - 3 \times 2 \\ & \quad \downarrow \\ & = 8 - 6 \\ & = 2 \end{aligned}$$

$$\begin{aligned} (b) \quad & (8 - 3) \times 2 \\ & \quad \downarrow \\ & = 5 \times 2 \\ & = 10 \end{aligned}$$

---

$$\begin{aligned} 4(a) \quad & 40 \div (4 \div 2) \\ & \quad \downarrow \\ & = 40 \div 2 \\ & = 20 \end{aligned}$$

$$\begin{aligned} (b) \quad & (40 \div 4) \div 2 \\ & \quad \downarrow \\ & = 10 \div 2 \\ & = 5 \end{aligned}$$

---

$$\begin{aligned} 5(a) \quad & (40 \div 4) \times 2 \\ & \quad \downarrow \\ & = 10 \times 2 \\ & = 20 \end{aligned}$$

$$\begin{aligned} (b) \quad & 40 \div (4 \times 2) \\ & \quad \downarrow \\ & = 40 \div 8 \\ & = 5 \end{aligned}$$

---

## **THE FINAL STEP IS : INDICES**

Instead of writing  $2 \times 2 \times 2 \times 2 \times 2$  we can just write  $2^5$

So  $3^4$  does not equal  $3 \times 4$  but  $3 \times 3 \times 3 \times 3 = 81$

Things get a little bit confusing here but just do the following:

$$\begin{aligned} & 2 + 10 \times 3^2 && \text{first we do indices} \\ = & 2 + 10 \times 9 && \text{now we do } \times \\ = & 2 + 90 && \text{and finally do } + \\ = & 92 \end{aligned}$$

---

However in this problem:

$$\begin{aligned} & (2 + 4) \times 3^2 - 5 && \text{first we do brackets} \\ = & 6 \times 3^2 - 5 && \text{now we do indices} \\ = & 6 \times 9 - 5 && \text{then } \times \\ = & 54 - 5 && \text{and finally subtract} \\ = & 49. \end{aligned}$$

---

Also note that:  $\frac{7+5}{9-6}$  is the same as though there were brackets  $\frac{(7+5)}{(9-6)}$

And this means:  $(7+5) \div (9-6) = \frac{12}{3} = 4$

---

Putting ALL these ideas together we can make a “word” to help remember them:

**B I D M A S**

Where B stands for BRACKETS

I stands for INDICES

$\left. \begin{array}{l} \mathbf{D} \text{ stands for DIVISION} \\ \mathbf{M} \text{ stands for MULTIPLICATION} \end{array} \right\}$	note: Division is not really BEFORE Multiplication. They have equal priority.
$\left. \begin{array}{l} \mathbf{A} \text{ stands for ADDITION} \\ \mathbf{S} \text{ stands for SUBTRACTION} \end{array} \right\}$	note: Addition is not really BEFORE Subtraction. They also have equal priority.

Sometimes the BIDMAS order does not seem to hold rigidly:

eg

$$\begin{aligned} & (2^3 - 5)^2 \quad \text{because we can't do the Brackets before we do the Index } 2^3 \\ &= (8 - 5)^2 \\ &= (3)^2 \\ &= 9 \end{aligned}$$
